HAB Task Force - Background

1990s

2010s-Present

Hysteria over Pfiesteria An Atlantic Coast mystery

Pfiesteria (fih-STEER-ee-ah) has been causing hysteria along the Atlantic coast. Just the name *pfiesteria* sounds kind of scary, doesn't it? Well, you'll be glad to know that it is not contagious or infectious. You can't catch it like you can a cold. Okay, but, what is it? Pfiesteria is a creature, or organism that generally falls under the heading "algae". Though it's very small (0.007 of a millimeter wide) and can't be seen

presence of fish, pfiesteria transforms from an inactive cyst to a cyst that produces a poison. Pfiesteria uses this poison to stun fish, making it easier to

Unfortunately, scientists still do not know a lot about pfiesteria, but research is under way in Maryland, Delaware, and North Carolina, where pfiesteria is most widespread. Many researchers believe that pfiesteria has

yet form of pfiesteria

War waged against pfiesteria
Sick fish close down third river
Doctors affirm link between pfiesteria and human illness

Holsinger and Everton 2016

The Phytoplankton Analysis Laboratory at Old Dominion University has been a Primary Task Force member of the Virginia Harmful Algae Bloom Task Force (HABTF) for over 30 years, and along with the Virginia Institute of Marine Science at the College of William and Mary, works with members of the VA HABTF Rapid Response Team to provide taxonomic, molecular, and toxin analyses used to identify and describe Harmful Algal Blooms in marine, tidal, and freshwaters of Virginia.

Algae blooms 101

The term algae bloom is inexact and subjective:

- a large population of phytoplankton
- extremely high cell densities of phytoplankton (greater than 20,000 to 100,000 cells per mL)
- a proliferation of phytoplankton dominated by a single or a few species
- a visible accumulation of phytoplankton at the water surface

What are harmful algae blooms (HAB)?

An algal bloom may be called harmful because of:

- reductions in dissolved oxygen concentrations
- alterations in aquatic food webs
- unsightly scums along shorelines
- production of taste-and-odor compounds that cause unpalatable drinking water and fish flesh
- the production of toxins potent enough to poison aquatic and terrestrial organisms

What are harmful algae blooms (HAB)?

An algal bloom may be called harmful because of:

- reductions in dissolved oxygen concentrations
- alterations in aquatic food webs
- unsightly scums along shorelines
- production of taste-and-odor compounds that cause unpalatable drinking water and fish flesh
- **the production of toxins potent enough to poison aquatic and terrestrial organisms**

What are cyanobacterial harmful algae blooms (CyanoHAB)?

Many different types of algae can cause harmful algal blooms in marine, tidal, and freshwater ecosystems.

The most frequent and severe blooms in non-tidal surface freshwaters in Virginia are caused by cyanobacteria, an organism with the potential for the production of toxins potent enough to adversely affect human health.

Cyanobacteria:

- are naturally occurring
- are true bacteria with a prokaryotic cell structure (cells that lack membrane-bound nuclei)
- have photosynthetic pigments like eukaryotes (cells with membrane-bound nuclei)

Because cyanobacteria are functionally algae-like (primary producers) in aquatic ecosystems, they are considered to be part of algal communities.

Figure 2. Harmful algal bloom species representative of major taxonomic algal groups along the freshwater-to-marine continuum.

What are cyanobacterial harmful algae blooms (CyanoHAB)?

Many different types of algae can cause harmful algal blooms in marine, tidal, and freshwater ecosystems.

The most frequent and severe blooms in non-tidal surface freshwaters in Virginia are caused by cyanobacteria, an organism with the potential for the production of toxins potent enough to adversely affect human health.

Pennate diatom

Filamentous green algae

Filamentous green algae

Not all freshwater HAB events are caused by cyanobacteria!

Euglena – motile stage

Euglena – palmella stage

Mallomonas

Cyanobacteria taxa groups

Potentially toxigenic (PTOX) filamentous and colonial cyanobacteria genera observed in Virginia

PTOX - not all cyanobacteria taxa produce toxins, different toxins may be produced by multiple taxa, and some taxa may produce multiple toxins over the course of a bloom

Toxin categories associated with select filamentous and colonial cyanobacteria genera observed in fresh and tidal waters of Virginia (2017-2022).

	Dermatoxins			Hepatotoxins			Neurotoxins			Taste and odor		
	LYN	APL	LPS	CYL ^{2,3}	MC ^{2,3}	NOD ²	ATX ^{2,3}	BMMA	NEO	SAX ^{2,3}	GEOS	MIIB
<i>Anabaena</i> ¹			X	X	X		X	X	X	X	X	X
<i>Anabaenopsis</i> ¹			X		X

¹ Taxa which have been observed in samples collected at Lake Anna during rapid responses for Harmful Algal Bloom (HAB) reports.

² Toxin categories analyzed by ELISA during rapid responses for HAB reports (MC & NOD by ADDA since 2015, CYL since 2017, and ATX & SAX since 2020).

³ Toxins with an action threshold (CYL 15ppb, MC 8ppb, ATX 8ppb, and SAX 4ppb) in VA.

Toxin data included in this table are based on documented production in laboratory cultures and data based on circumstantial evidence, such as co-occurrence of genera and toxin or taste-and-odor compounds in environmental samples. LYN, lyngbyatoxin-a; APL, aplysiatoxins; LPS, lipopolysaccharides; CYL, cylindrospermopsins; MC, microcystins; NOD, nodularins; ATX, anatoxins; BMMA, β-N-methylamino-L-alanine; NEO, neosaxitoxins; SAX, saxitoxins; GEOS, geosmin; MIB, 2-methylisoborneol.

Analysis of HAB event samples

Taxonomic enumeration

Scan is conducted to identify dominant species

Abraxis microcystins (ADDA) ELISA

8.0 ppb 0.15ppb - 5.0ppb (higher w/dilution)

Abraxis cylindrospermopsin ELISA

15.0 ppb 0.05ppb - 2.0ppb (higher w/dilution)

Abraxis anatoxin-a ELISA

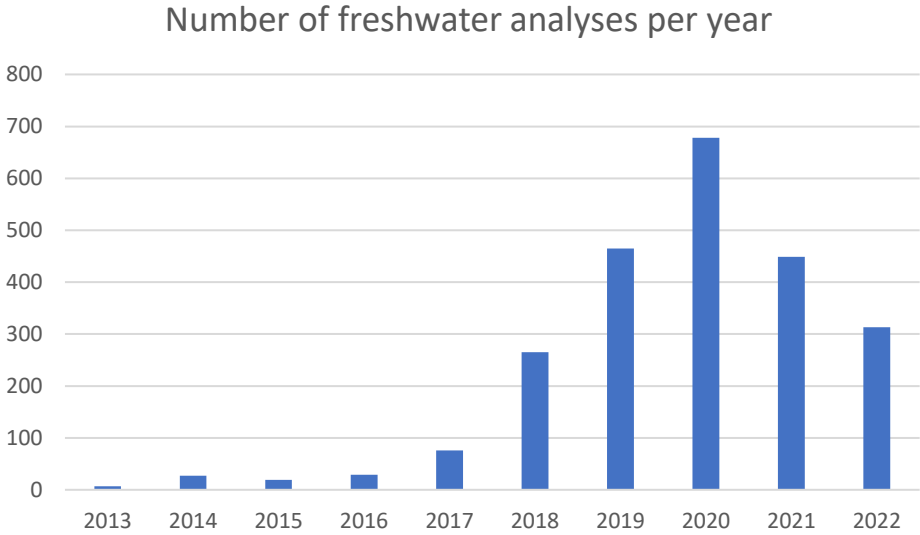

8.0 ppb 0.15ppb - 5.0ppb (higher w/dilution)

Abraxis saxitoxin ELISA

4.0 ppb 0.02ppb - 0.4ppb (higher w/dilution)

2017 – 2022 HAB TF Overview

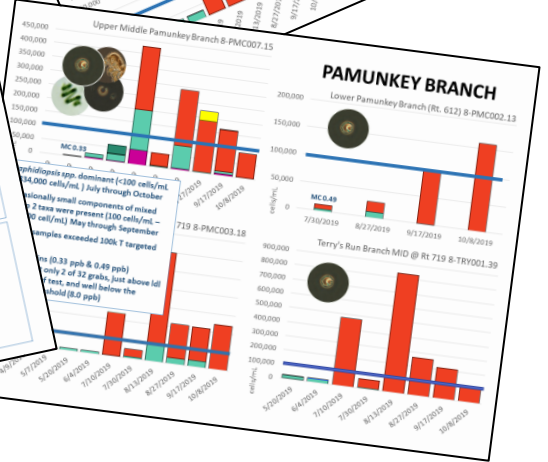

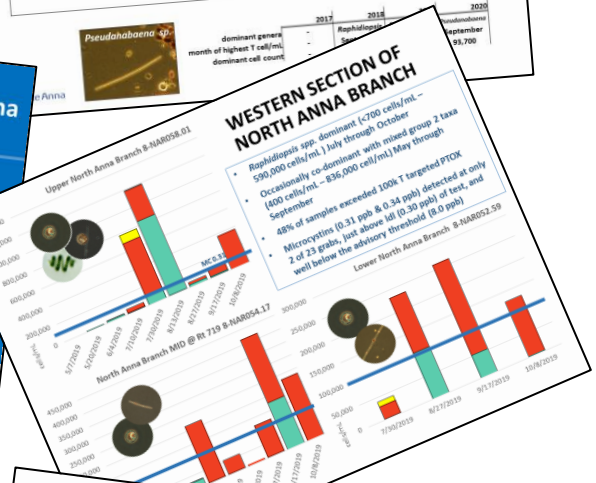

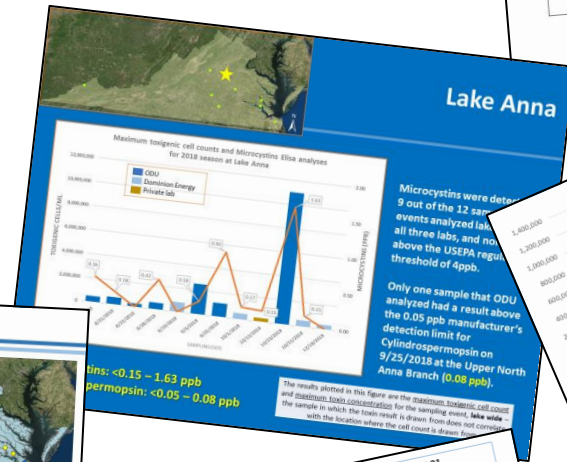

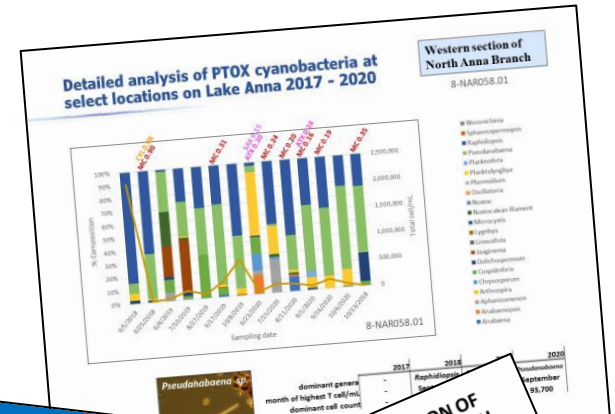

2022 Freshwater Overview

- **549 samples under our VDH contract**
 - **484 estuarine samples**
 - **65 inland freshwater samples**
 - **77 of these were associated with a rapid HAB response**
 - **12 samples from tidal waters**
 - **65 inland freshwater samples**
- **Freshwater breakdown**
 - **65 samples received**
 - **313 analyses conducted**
 - **65 taxonomic enumerations**
 - **62 microcystins by ELISA**
 - **62 cylindrospermopsin by ELISA**
 - **62 anatoxin-a by ELISA**
 - **62 saxitoxin by ELISA**

Overview of VDH targeted PTOX cell densities on Lake Anna since 2017

- SECTION OF NORTH ANNA BRANCH**
- North Anna Branch - Upper 8-NAR058.01
 - PTOX 1,000 - 185,000 cells/ml
 - North Anna Branch - Lower 8-NAR052.59
 - PTOX 0 - 125,000 cells/ml
 - North Anna Branch - MID (Rt. 719) 8-NAR054.17
 - PTOX 9,000 - 125,000 cells/ml
 - Pamunkey Branch - MID (Rt. 719) & PMC0003.18
 - PTOX 1,000 - 47,000 cells/ml
 - Pamunkey Branch - Upper 8-PMC007.15
 - PTOX 9,000 - 42,000 cells/ml
 - Terry's Run Branch - MID (Rt. 719) 8-TRY001.39
 - PTOX 19,000 - 89,000 cells/ml
 - State Park Beach
 - PTOX 0 - 34,000 cells/ml
 - North Anna Branch @ Split 8-NAR050.90
 - PTOX 1,000 - 78,000 cells/ml
 - North Anna Branch @ Rt 208 8-NAR047.69
 - PTOX 23,000 - 138,000 cells/ml

2017 freshwater blooms

- 2010-2017 survey identifies potentially toxic cyanobacteria in ~1/2 of lakes surveyed
- Continued prevalence of Microcystis blooms as well as increasing concern of filamentous cyanobacteria blooms

Virginia Lake Survey 2010-2017

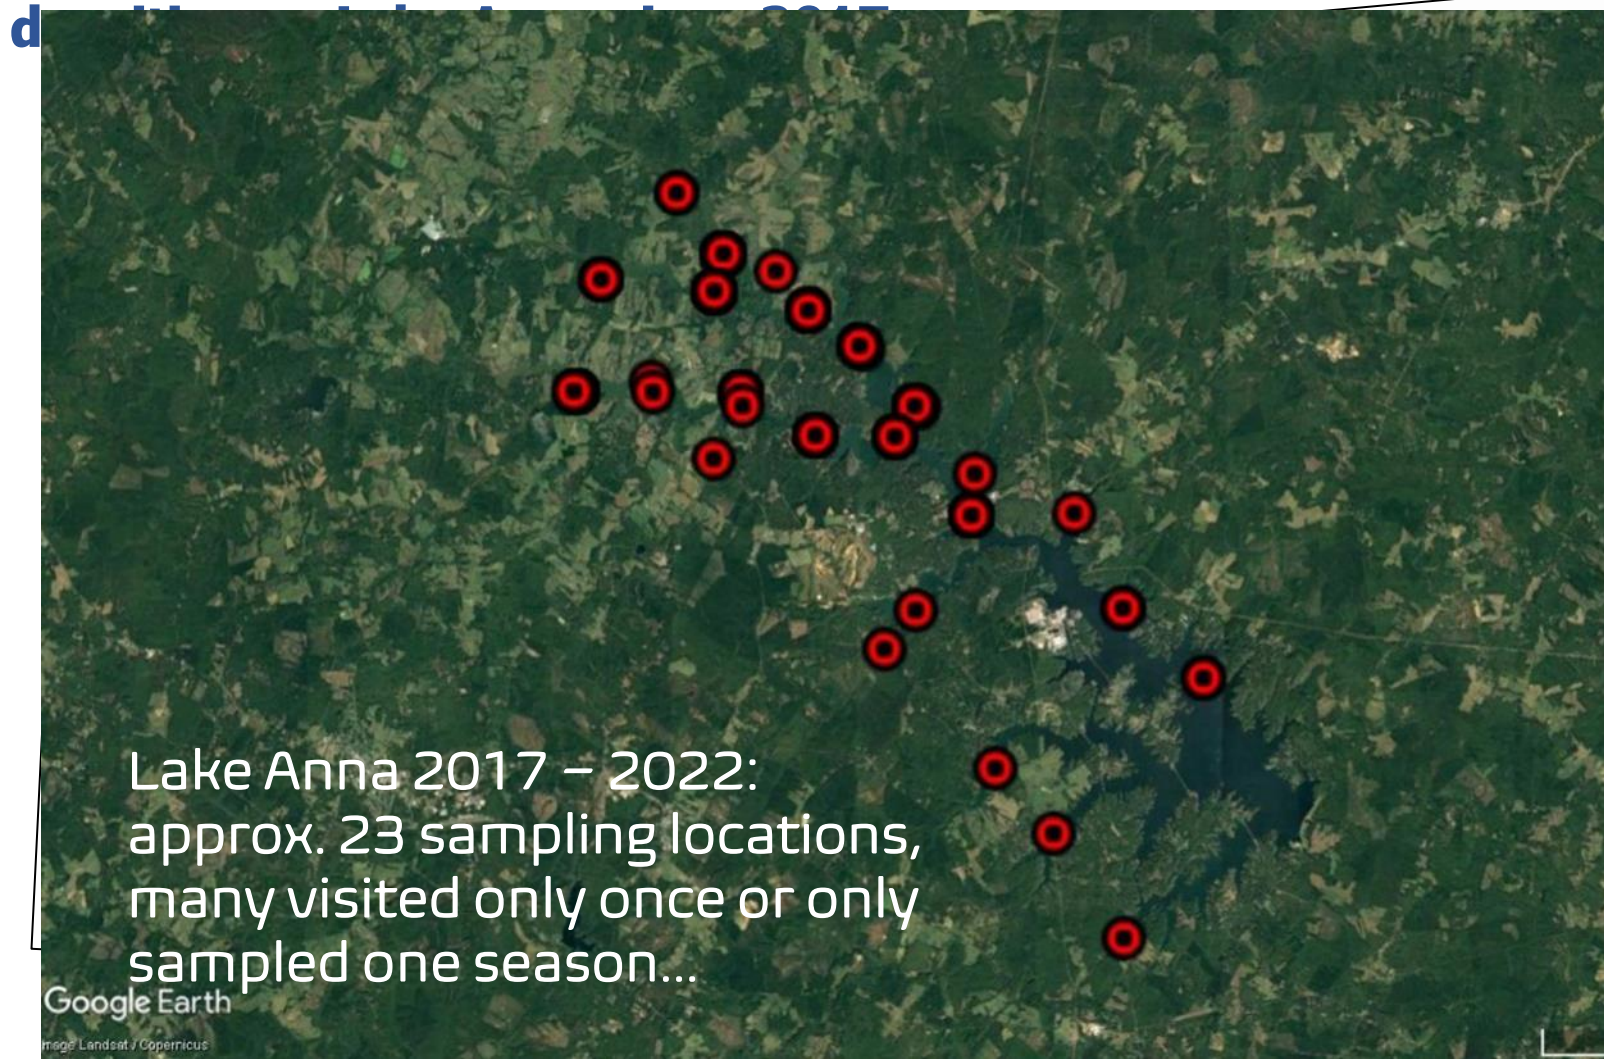

BE AWARE OF ALGAE BLOOMS

Overview of VDH targeted PTOX cell

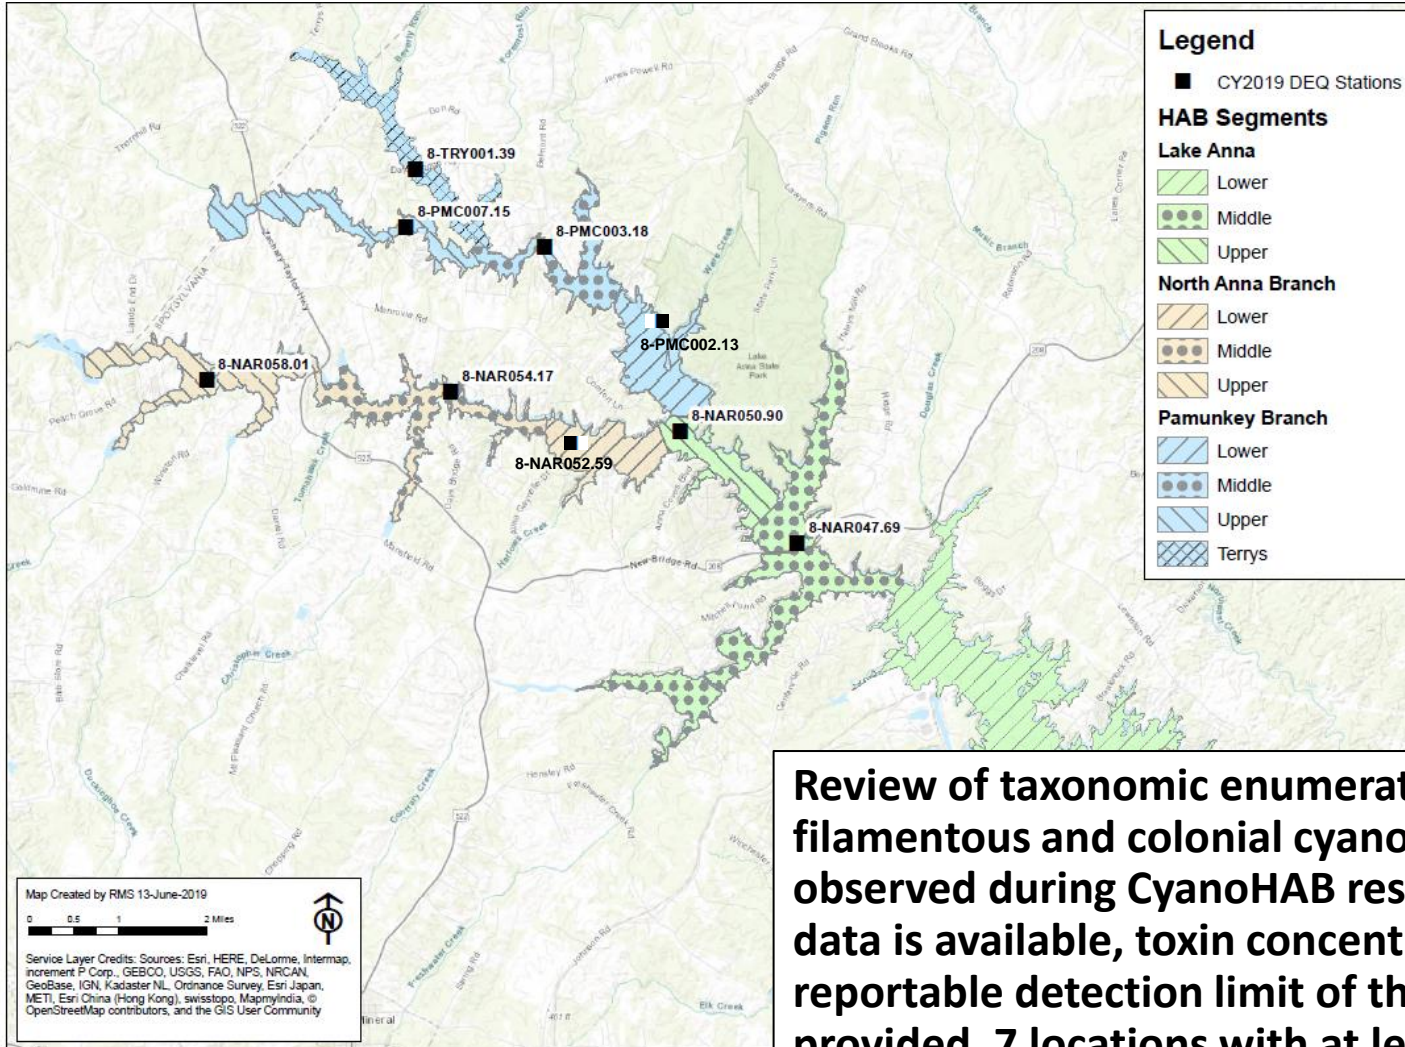

WESTERN SECTION OF NORTH ANNA BRANCH

- PTOX 0 – 500
- North Anna Branch @ Split 8-NAR050.90
- PTOX 1,000 – 78,000 cell/ml
- North Anna Branch @ RT 208 8-NAR047.69
- PTOX 23,000 – 138,000 cell/ml

Detailed analysis of PTOX cyanobacteria at select locations on Lake Anna 2017 - 2022

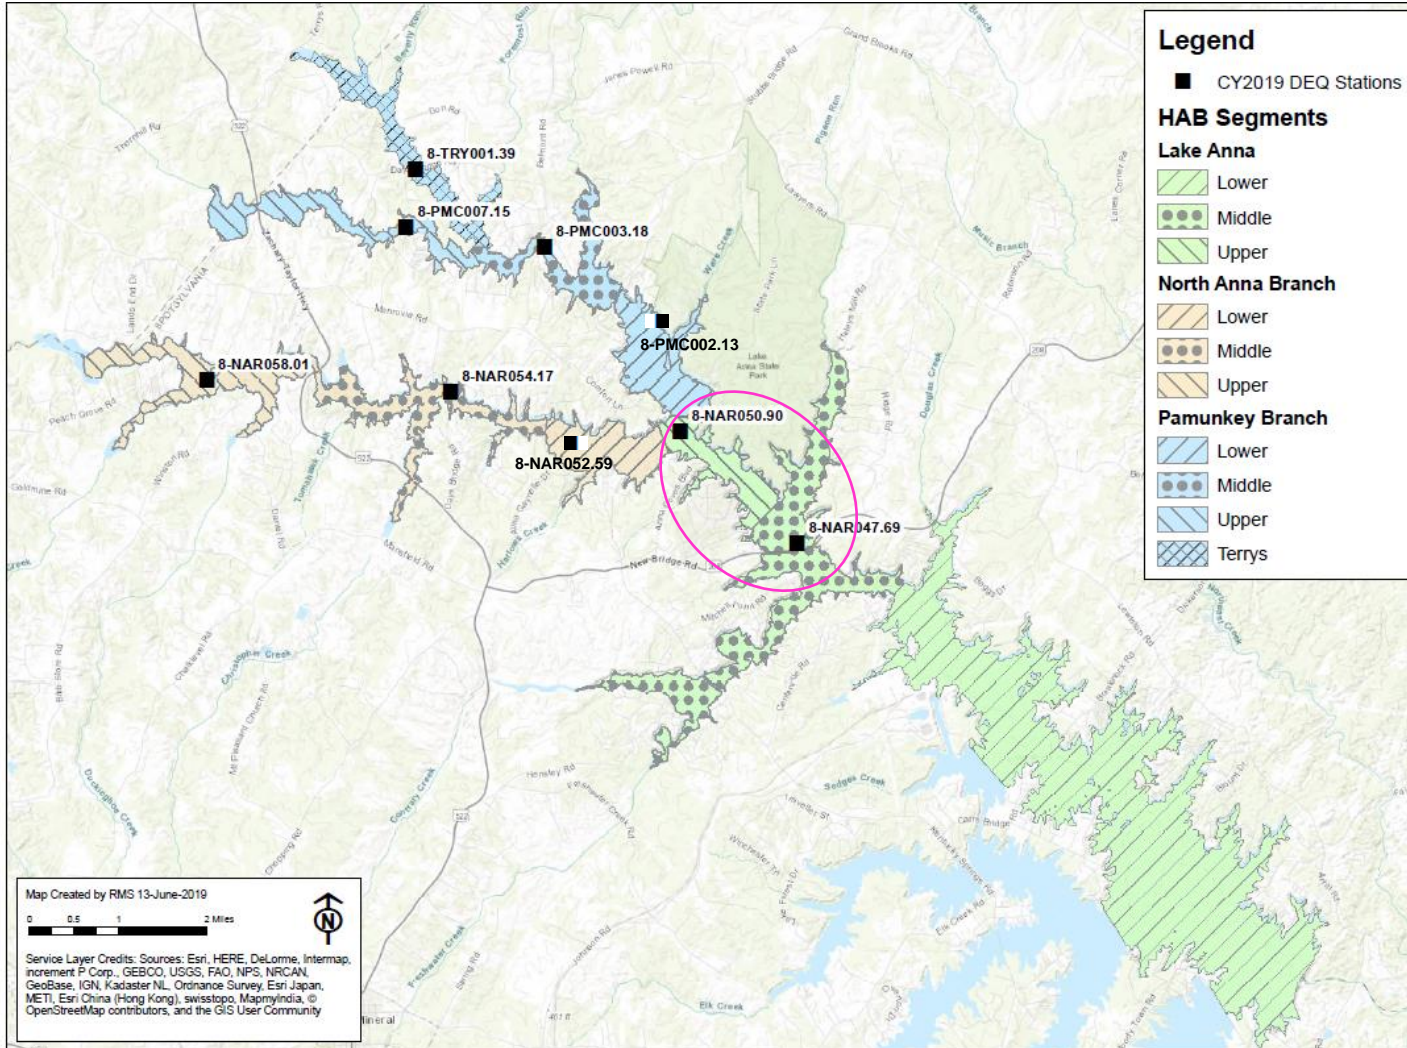

Review of taxonomic enumerations of filamentous and colonial cyanobacteria observed during CyanoHAB responses. Where data is available, toxin concentrations above the reportable detection limit of the test (ELISA) are provided. 7 locations with at least 5 sampling events over a minimum of 2 seasons.

Detailed analysis of PTOX cyanobacteria at select locations on Lake Anna 2017 - 2022

Lower section of North Anna Branch

Lake Anna toxin concentrations 2017 - 2022

Trends in toxin concentrations and associated filamentous PTOX cyanobacteria

- toxins generally remain below or just above reportable detection limits at regularly monitored locations
- the presence or absence of hepatotoxins is not a predictor of the presence or absence of neurotoxins
- *Raphidiopsis* is usually a major component of the community when MC is present
- *Pseudanabaena*, *Planktolyngbya*, *Chrysothrix*, *Cuspidothrix*, and *Dolichospermum* are also associated with the presence of MC and other toxins

Understanding the Lake Anna phytoplankton community and potential for toxin production is complicated

Lines of inquiry being explored to complement current projects by LACA and DEQ :

- Full algal taxonomy on Lake Anna to better understand the relationship between the cyanobacteria community within the greater phytoplankton community, and how it may be influenced by environmental conditions and/or mitigation practices (treatments)
- Joint QA/QC with LACA and NOAA for clarity of taxonomic nomenclature
- Developing qPCR methods to determine the presence of cyanotoxin producing genes
- Mapping akinete seed banks to identify potential bloom initiation sites
- Isolation of cyanobacterial cultures to examine growth kinetics (Aliyah Downing, PhD candidate)

Thank you.
