Estimation of COVID-19 Impact in Virginia

June 3rd, 2020

(data current to June 2nd)

Biocomplexity Institute Technical report: TR 2020-070

UNIVERSITY of VIRGINIA

BIOCOMPLEXITY INSTITUTE

biocomplexity.virginia.edu

Who We Are

- Biocomplexity Institute at the University of Virginia
  - Using big data and simulations to understand massively interactive systems
- Over 20 years of crafting and analyzing infectious disease models
  - Pandemic response and support for Influenza, Ebola, Zika, others

Points of Contact

Bryan Lewis

UNIVERSITY of VIRGINIA

BIOCOMPLEXITY INSTITUTE

Overview

- **Goal**: Understand impact of COVID-19 mitigations in Virginia
- **Approach:**
  - Calibrate explanatory mechanistic model to observed cases
  - Project infections through the end of summer
  - Consider a range of possible mitigation effects in "what-if" scenarios
- **Outcomes:**
  - Ill, Confirmed, Hospitalized, ICU, Ventilated, Death
  - Geographic spread over time, case counts, healthcare burdens

Key Takeaways

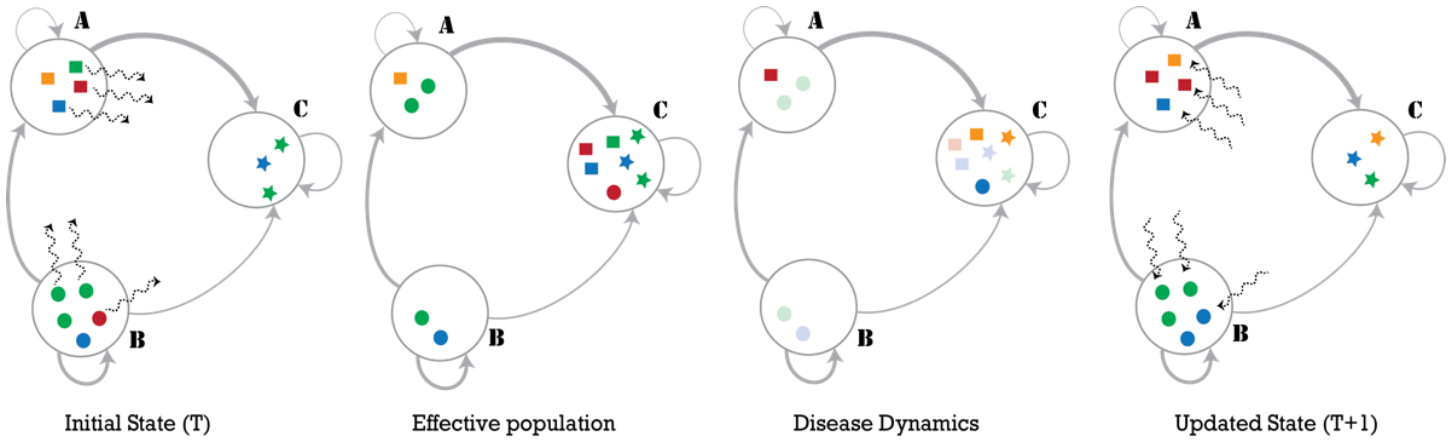
Projecting future cases precisely is impossible and unnecessary.
Even without perfect projections, we can confidently draw conclusions:

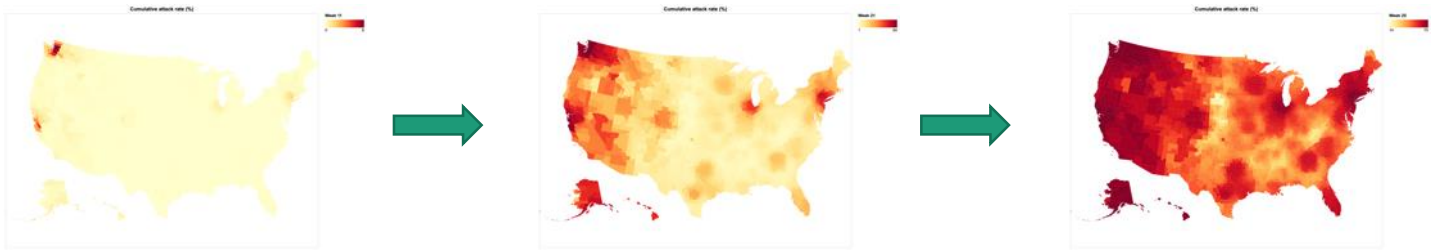
- **We are in a period of transition, shifting to sustaining control through test and trace and other mitigations rather than strict social distancing.**
- Model update this week shows possible paths forward, rebounds with and without new mitigations, uncertainty remains on timing of this transition.
- As fewer people “stay home” we observe a small rebound in growth rate.
- **Intensity of rebound** depends on degree of social distancing relaxation; **intensity of new mitigations** depends on testing volumes and tracing effectiveness.
- The situation is changing rapidly. Models will be updated regularly.

Model Configuration and Data Analysis

Simulation Engine – PatchSim

- Metapopulation model
  - Represents each population and its interactions as a single patch
  - 133 patches for Virginia counties and independent cities
- Extended SEIR disease representation
  - Includes asymptomatic infections and treatments
- Mitigations affect both disease dynamics and population interactions
- Runs fast on high-performance computers
  - Ideal for calibration and optimization





Venkatramanan, Srinivasan, et al. "Optimizing spatial allocation of seasonal influenza vaccine under temporal constraints." *PLoS Computational Biology* 15.9 (2019): e1007111.

Model Configuration

- **Transmission:** Parameters are calibrated to the observed case counts
  - **Reproductive number:** 2.1 - 2.3
  - **Infectious period** (time of infectiousness before full isolation): 3.3 to 5 days
- **Initial infections:** Start infections from confirmed cases by county
  - Timing and location based on onset of illness from VDH data
  - Assume 15% detection rate, so one confirmed case becomes ~7 initial infections
- **Mitigations:** Intensity of social distancing rebound and control sustaining mitigations into the future are unknowable, thus explored through 5 scenarios

Mitigation Scenarios:
Rebound Intensity x Detection Levels

Pause from Social Distancing: Began on March 15th

- Lifted on May 15th (61 days), with two-week delay (75 days) for select counties*
- **Intensity**: Social distancing pauses and significantly reduces case growth

Intensity of Rebound: Relaxation of social distancing measures increases interactions in society, leading to two levels of transmission rates:

- **Light:** Interactions return to 1/6th of pre-pandemic levels, moderate increase in transmission
- **Strong:** Interactions return to 1/3rd of pre-pandemic levels, stronger increase in transmission
- **Full Rebound**: Interactions return completely (100%) to pre-pandemic levels, as a reference

Detection Control: Increased Testing Capacity coupled with infection control measures

- **Better Detection**: Plays a role by limiting the period of infectiousness before isolation

* Select counties as mentioned by recent releases from Governor Northam's office
https://www.governor.virginia.gov/newsroom/all-releases/2020/may/headline-856741-en.html
https://www.governor.virginia.gov/newsroom/all-releases/2020/may/headline-856796-en.html

Five Mitigation Scenarios

Scenario	Rebound Intensity	Better Detection	Name	Description
1	Strong	No	Strong	Strong Rebound, Detection same
2	Light	No	Light	Light Rebound, Detection same
3	Strong	Yes	Strong – BetterDetection	Strong Rebound, Detection improved
4	Light	Yes	Light – BetterDetection	Light Rebound, Detection improved
5	Full	No	Full Rebound	Return to No mitigation

Full Model Parameters

	Parameter	Values	Description
Transmission	Transmissibility (R_0)[1]	2.2 [2.1 – 2.3]	Reproductive number
	Incubation period[1]	5 days	Time from infection to infectious
	Infectious period[1]	3.3 - 5 days	Duration of infectiousness
	Infection detection rate[3]	15%	1 confirmed case becomes ~7 initial infections
	Percent asymptomatic[1]	50%	Infected individuals that don't exhibit symptoms
Resources	Onset to hospitalization[1]	5 days	Time from symptoms to hospitalization
	Hospitalization to ventilation[1]	3 days	Time from hospitalization to ventilation
	Duration hospitalized	8 days	Time spent in the hospital [4]
	Duration ventilated[2]	14 days	Time spent on a ventilator
	Percent hospitalized[1]	5.5% (~20% of confirmed)	Symptomatic individuals becoming hospitalized
	Percent in ICU[1]	20%	Hospitalized patients that require ICU
	Percent ventilated[1]	70%	ICU patients requiring ventilation

4 Personal communications, UVA Health and Sentara (~500 VA based COVID patients)

Recent Parameter Validation

New York State announced sero-prevalence survey results on May 2nd

- 15,000 antibody tests conducted randomly through the state at grocery stores
- **Total Attack Rate**: 12.3%

Estimation of undetected infections

- Total infections in NY = 2.46M, total of 300K confirmed cases
- Confirmed case detection = 12% of infections (close to 15% used in model)

Estimation of hospitalizations from infections

- Total infections in NY = 2.46M, total of 66K hospitalizations
- Hospitalizations = 2.7% of infections (close to 2.25% used in model)

Calibration Approach

- **Data:**
  - County level case counts by date of onset (from VDH)
  - Confirmed cases for model fitting
- **Model:** PatchSim initialized with disease parameter ranges from literature
- **Calibration:** fit model to observed data
  - Search transmissibility and duration of infectiousness
  - Markov Chain Monte Carlo (MCMC) particle filtering finds best fits while capturing uncertainty in parameter estimates
- **Project:** future cases and outcomes using the trained particles

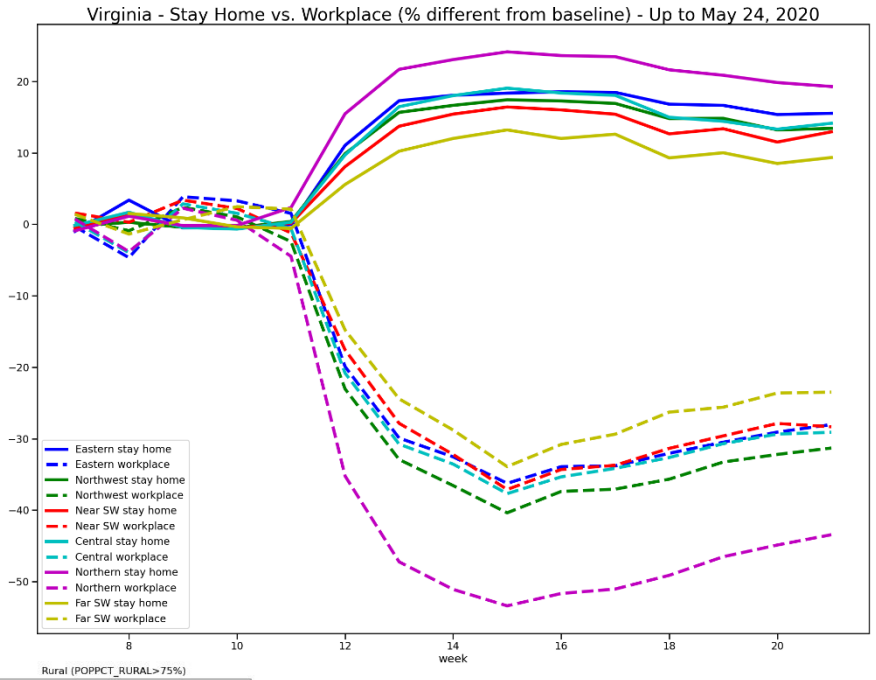
Impact of Interventions

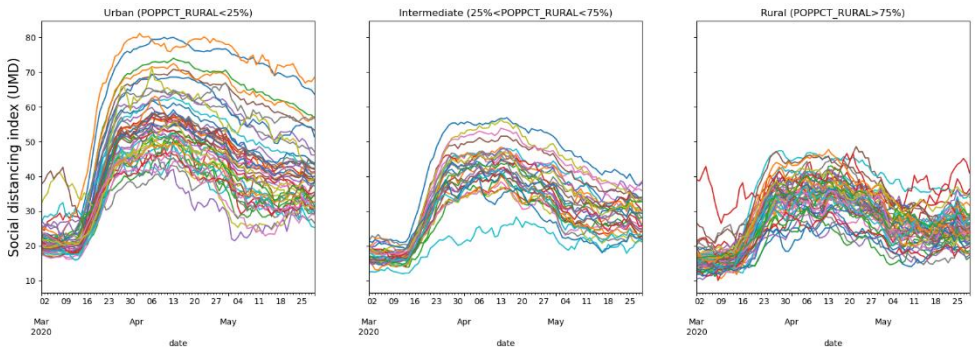
Estimating Effects of Social Distancing

Mobility data shows pause mid-March, slow rebound starting in May

Google Mobility data shows continued slow rebound
(as of May 24th)
https://www.google.com/covid19/mobility/

- Regional levels of Stay at home vs. Workplace
- 30% reduction of those staying at home
- **Trends**: Fewer at home, more at work





Urban – Rural divide shows in level of social distancing
https://data.covid.umd.edu

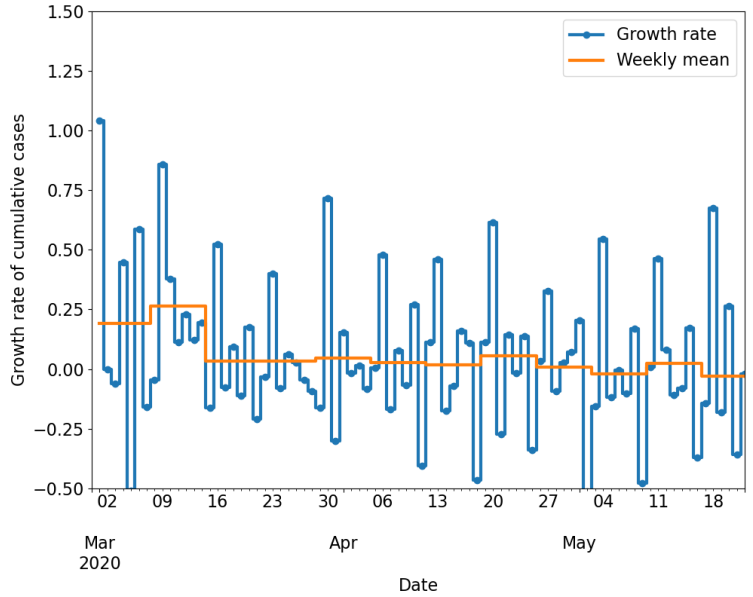
- Urban counties show more social distance, rural counties show less
- This is a biased measure, lower mobility accesses more services in urban areas

Weekly growth rate by date of onset

- Week before March 15 = 0.3
- Week after March 15 = -0.03 to 0.04

Crude reproductive number estimates

- 2.2 before March 15th
- 0.87 to 1.19 after March 15th

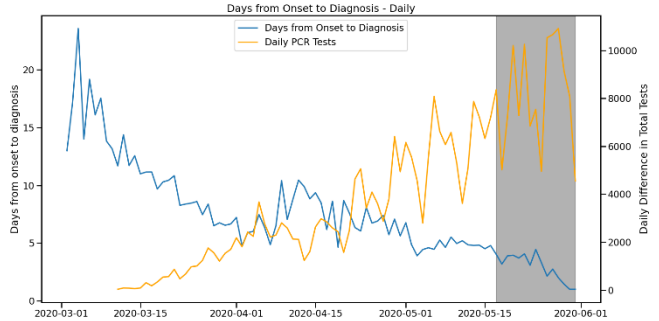


Estimating Effects of Better Detection

VDH data shows reductions in time from Symptom Onset to Diagnosis

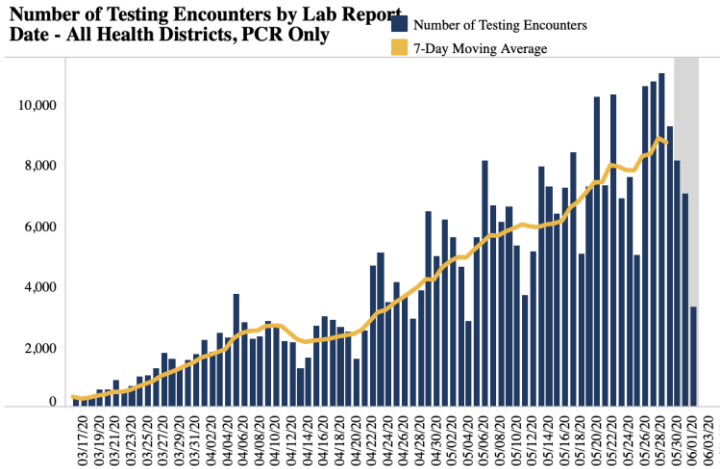
Days to Diagnosis drops ~30% in recent weeks

- Mid March to Late April = 7.2 days
- Late April to Mid May = 5.1 days
- Slight shift up from last week (6.8 and 4.8)

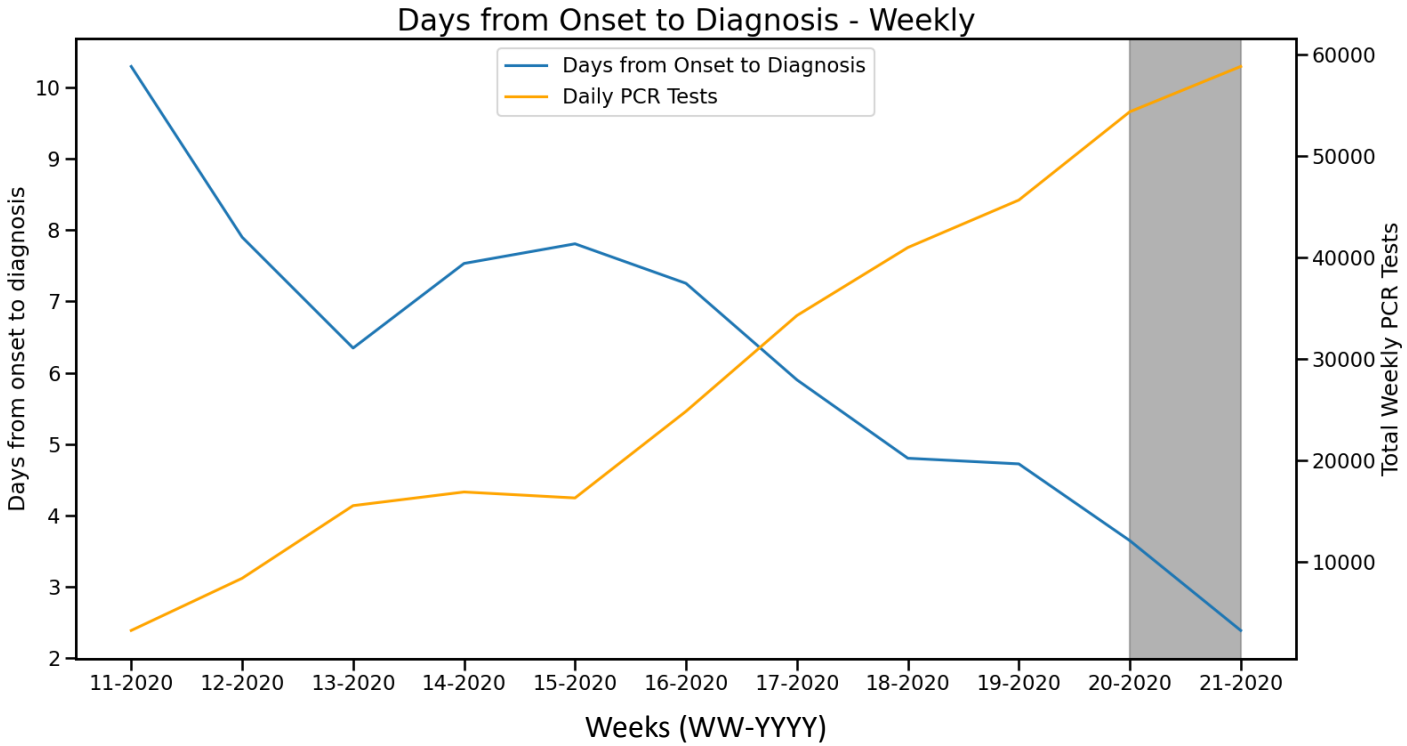


Testing Encounters increase

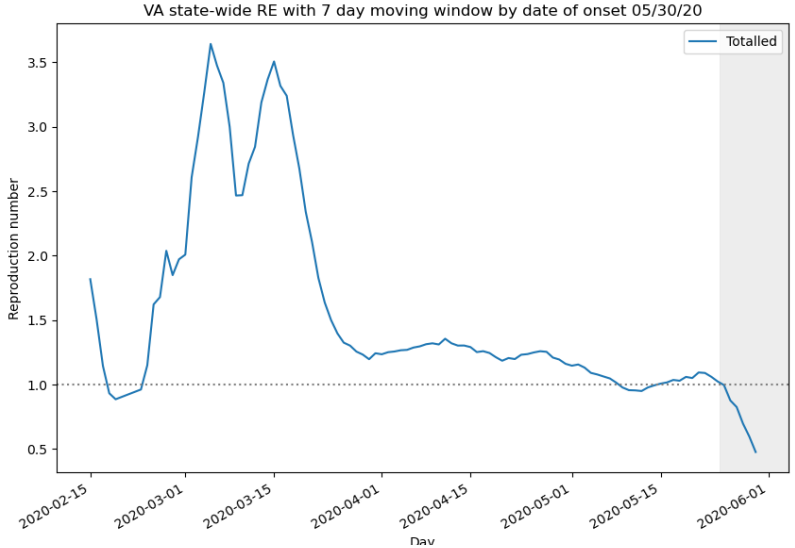
- Late April = ~4K / day
- Late May = ~10K / day

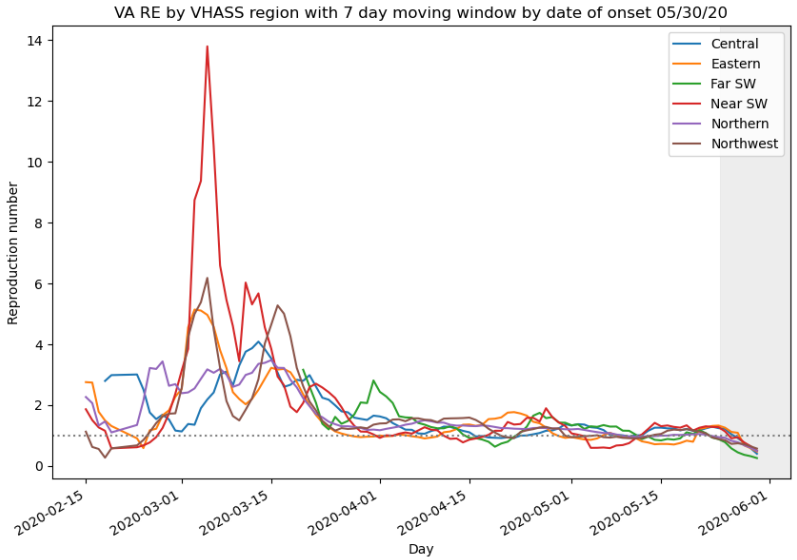


Accessed 5pm June 2, 2020
https://www.vdh.virginia.gov/coronavirus/



Estimating Daily Reproductive Number





Statewide and most regions follow similar pattern

- Spike, followed by a decline, to plateau, with recent upswing
- This week: overall decline, some regions up

Methodology

- Wallinga-Teunis method as implemented in EpiEstim[1] R package
- Based on Date of Onset of Symptoms
- Uses serial interval to estimate R_e over time: 6 days (2 day std dev)

Recent Estimates subject to revision as more data comes in

- Date of onset unstable in last 7-14 days

May 23rd Estimates

Region	Current Re	Diff Last Week
State-wide	1.060	0.105
Central	1.289	0.100
Eastern	1.314	0.625
Far SW	0.932	0.114
Near SW	1.282	0.038
Northern	0.983	0.053
Northwest	0.936	-0.164

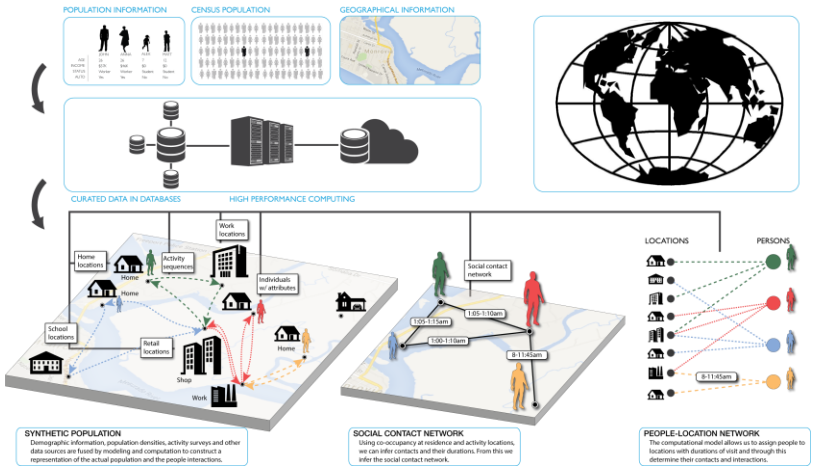
Agent-based Model (ABM)

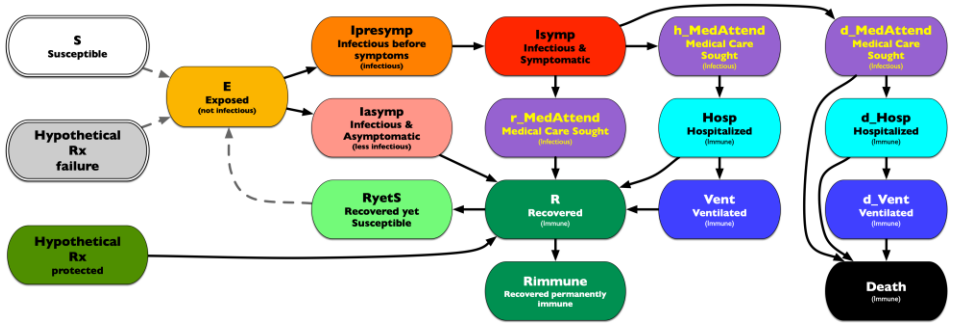
EpiHiper: Distributed network-based stochastic disease transmission simulations

- Assess the impact on transmission under different conditions
- Assess the impacts of contact tracing



Synthetic Population

- Census derived age and household structure
- Time-Use survey driven activities at appropriate locations



Detailed Disease Course of COVID-19

- Literature based probabilities of outcomes with appropriate delays
- Varying levels of infectiousness
- Hypothetical treatments for future developments

ABM Social Distancing Rebound Study Design

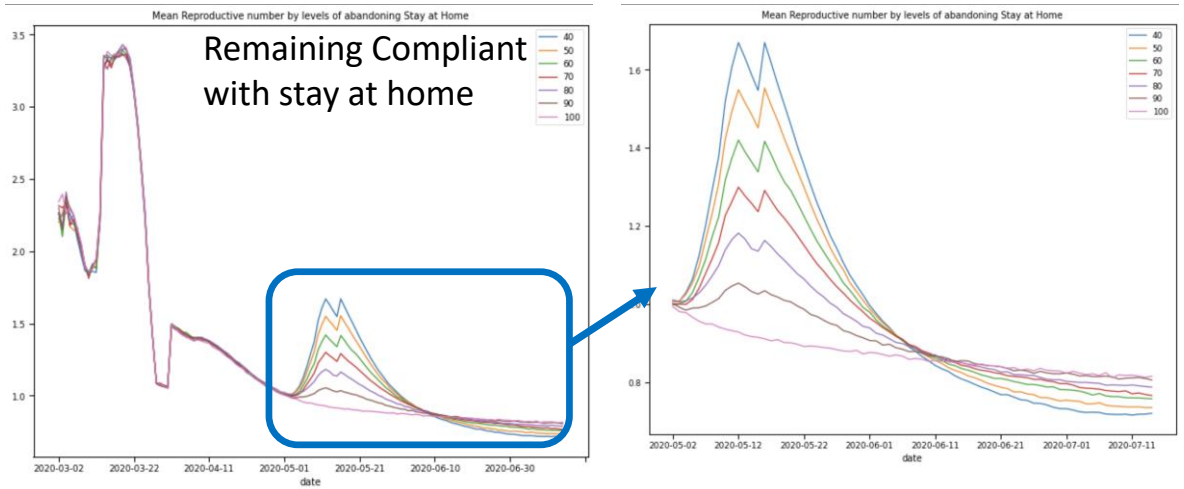
Study of ”Stay Home” policy adherence

- Calibration to current state in epidemic
- Implement “release” of different proportions of people from ”staying at home”

	date	best case	best guess	worst case	R
1	2020-05-10	664	852	1079	0.95
2	2020-05-17	666	841	1093	0.91
3	2020-05-24	617	768	1111	0.80
4	2020-05-31	547	705	1064	NA

Calibration to Current State

- Adjust transmission and adherence to current policies to current observations
- For Virginia, with same seeding approach as PatchSim



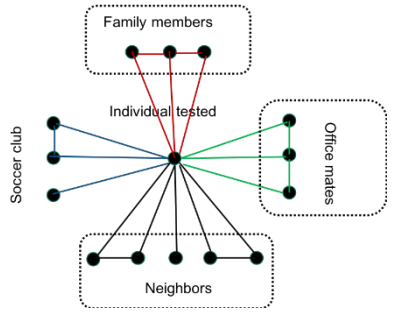
Impacts on Reproductive number with release

- After release, spike in transmission driven by additional interactions at work, retail, and other
- At 25% release (70-80% remain compliant)
- Translates to 15% increase in transmission, which represents a 1/6th return to pre-pandemic levels

Preliminary ABM Contact Tracing Study

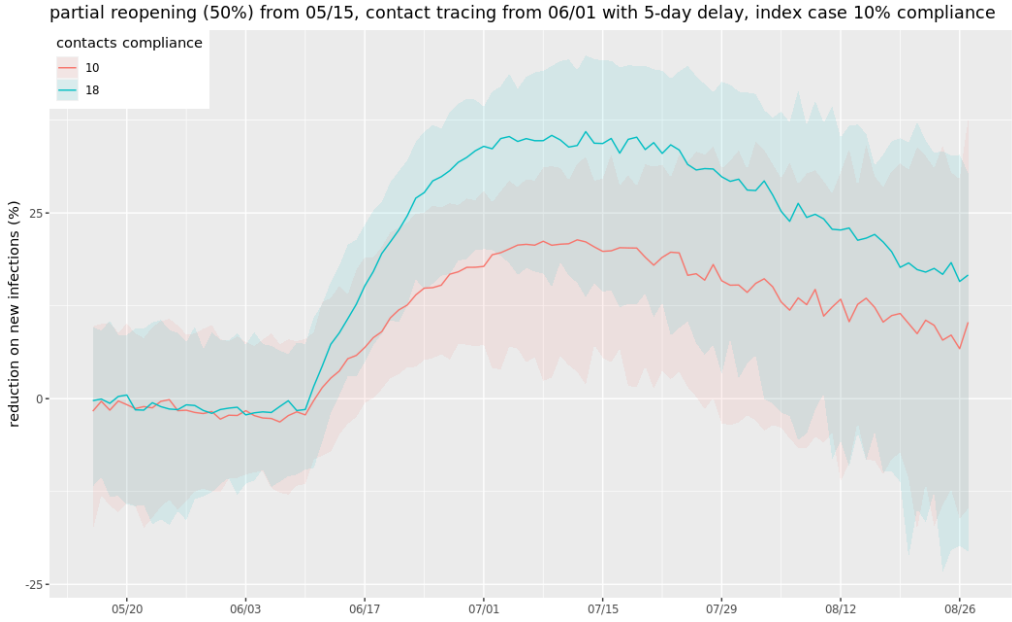
What reductions in cases can enhanced case and contact isolation achieve?

- Preliminary results suggest modest levels of compliance will have benefits
  - Must increase case finding and their compliance with isolation
  - Must have sufficient tracers to find contacts and urge isolation
- *Preliminary estimates* suggest the numbers of new infections can be reduced 20-30% with improved isolation of cases (10% more) and moderate compliance (10-18%) of contacts



Isolation of the tested person, and tracing of their family and close contacts.

name	description	timing
VHI (voluntary home isolation)	40% of symptomatic cases stay home for 14 days	throughout the pandemic
SC (school closure)	all schools are closed	from 03/13 to 08/28
RO (partial reopening)	a fraction of people who used to stay home continue doing so	from 05/15
CT (contact tracing)	a fraction f_1 of symptomatic cases are identified (as index cases) and isolated; a fraction f_2 of their close contacts (at least 2 hours every day) are traced and isolated at home	from 06/01



Future Interactions Drive Future Cases

Adherence to Social Distancing measures and Individual Choices about Personal Disease Control Practices will drive the next phase of the Epidemic

Challenges:

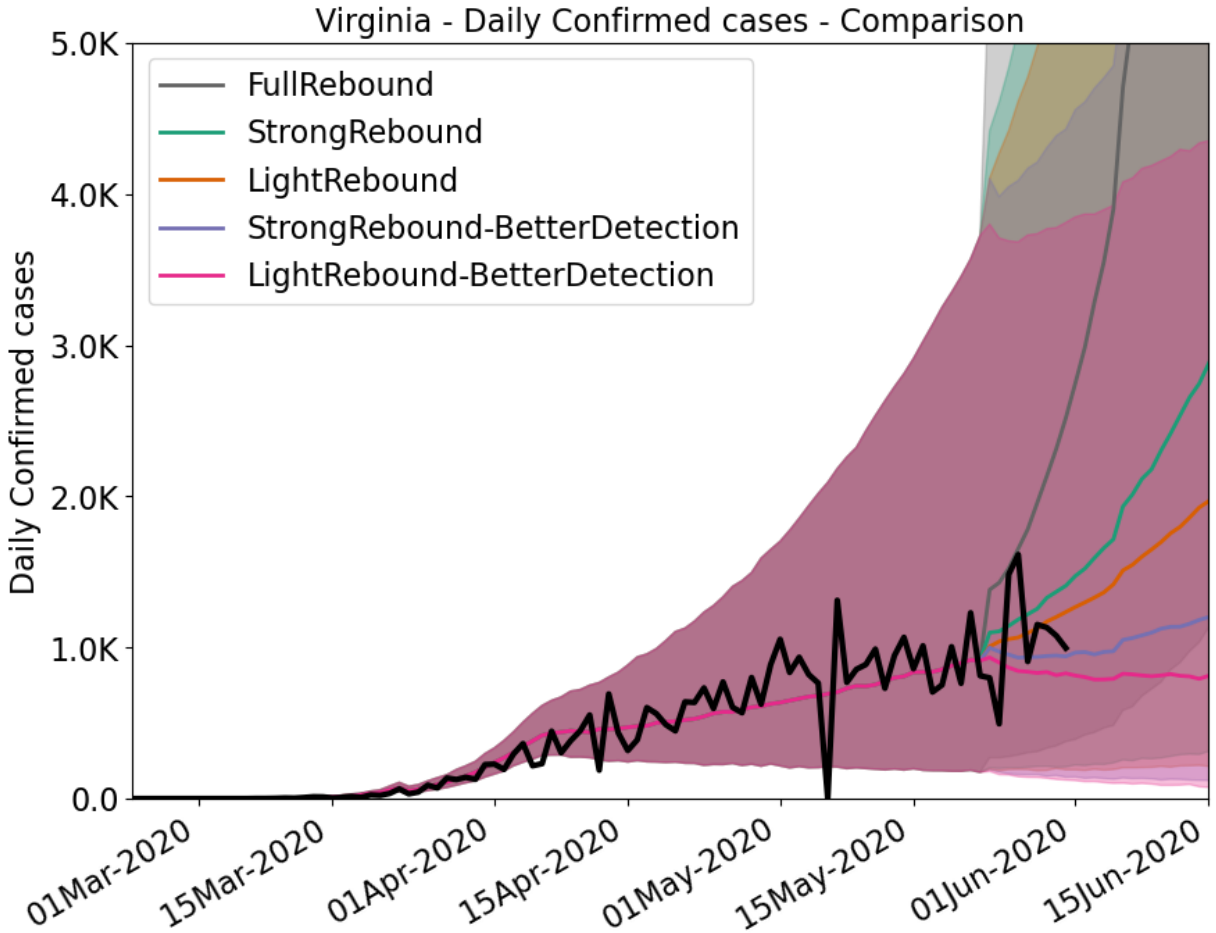
- Assessing the adherence with policies as actual behavior drives the epidemic
- Translating future policies to changes in transmission dynamics

Interactions can increase and cases can be driven lower, sustaining control

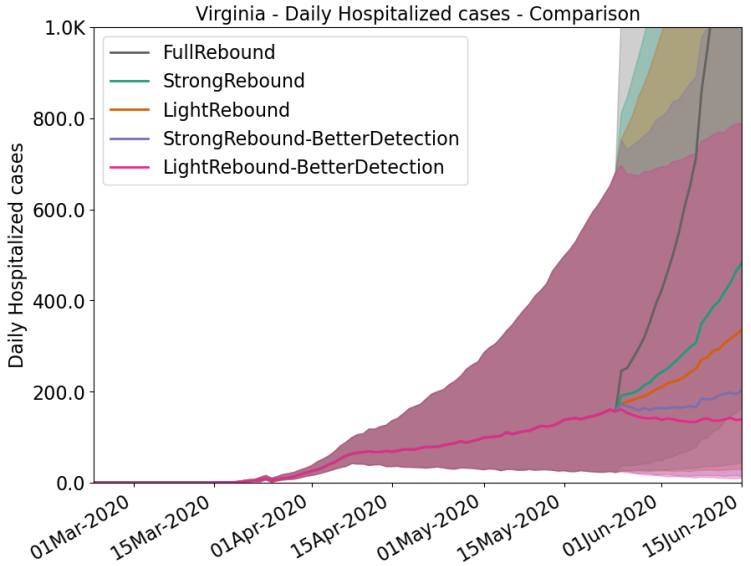
- Policies must carefully weigh local risk of spread, monitor local epidemiology, and tune policies and guidance to changing conditions
- Individuals must be ready to adhere to changes in policies and adopt good personal disease control practices

Short-term Projections

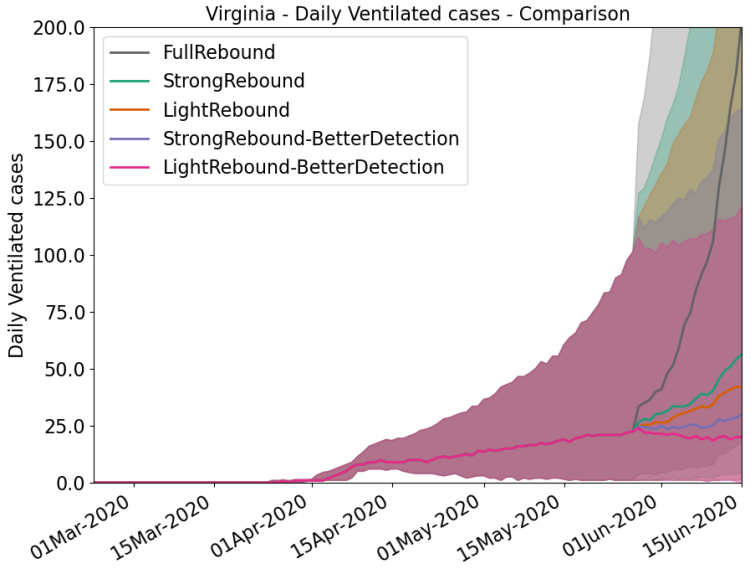
Confirmed cases



Hospitalizations



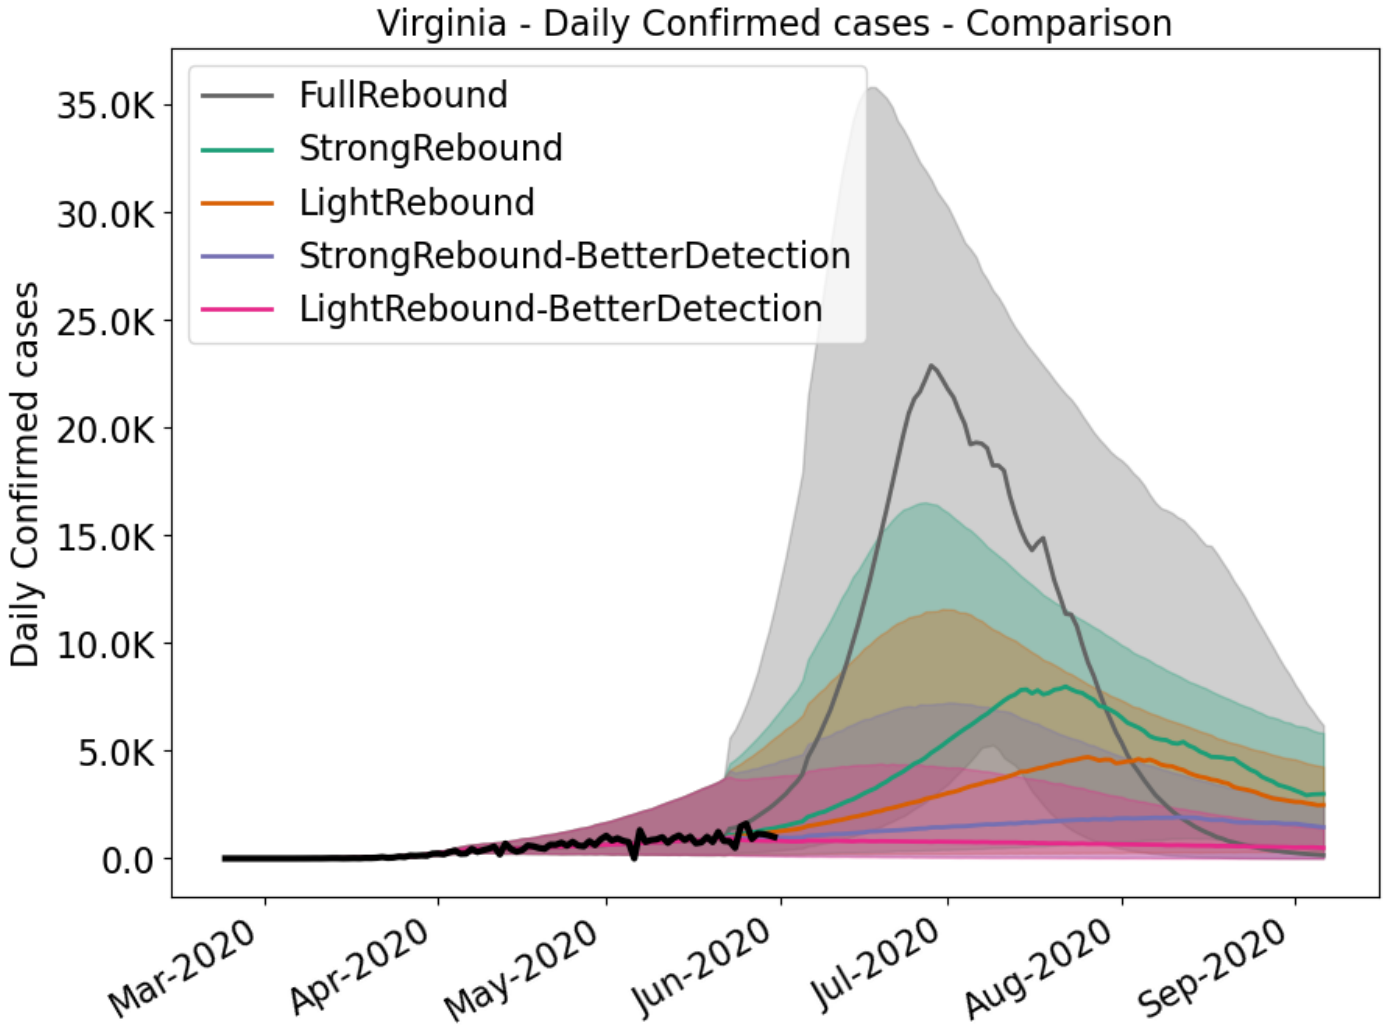
Ventilations



UNIVERSITY of VIRGINIA

BIOCOMPLEXITY INSTITUTE

Period of Transition: Sustaining Control



Weekly New Confirmed Cases*

Week Ending	Full Rebound	Light	Light – Better Detection
5/31/20	11,736	7,454	5,977
6/7/20	21,068	8,951	5,586
6/14/20	44,408	11,376	5,676
6/21/20	83,324	14,037	5,560
6/28/20	129,710	17,128	5,456
7/5/20	146,863	20,539	5,330
7/12/20	132,152	24,076	5,202
7/19/20	108,726	27,570	5,024
7/26/20	80,377	30,328	4,822
8/2/20	50,979	30,814	4,658
8/9/20	27,978	29,894	4,438
8/16/20	14,335	27,090	4,210

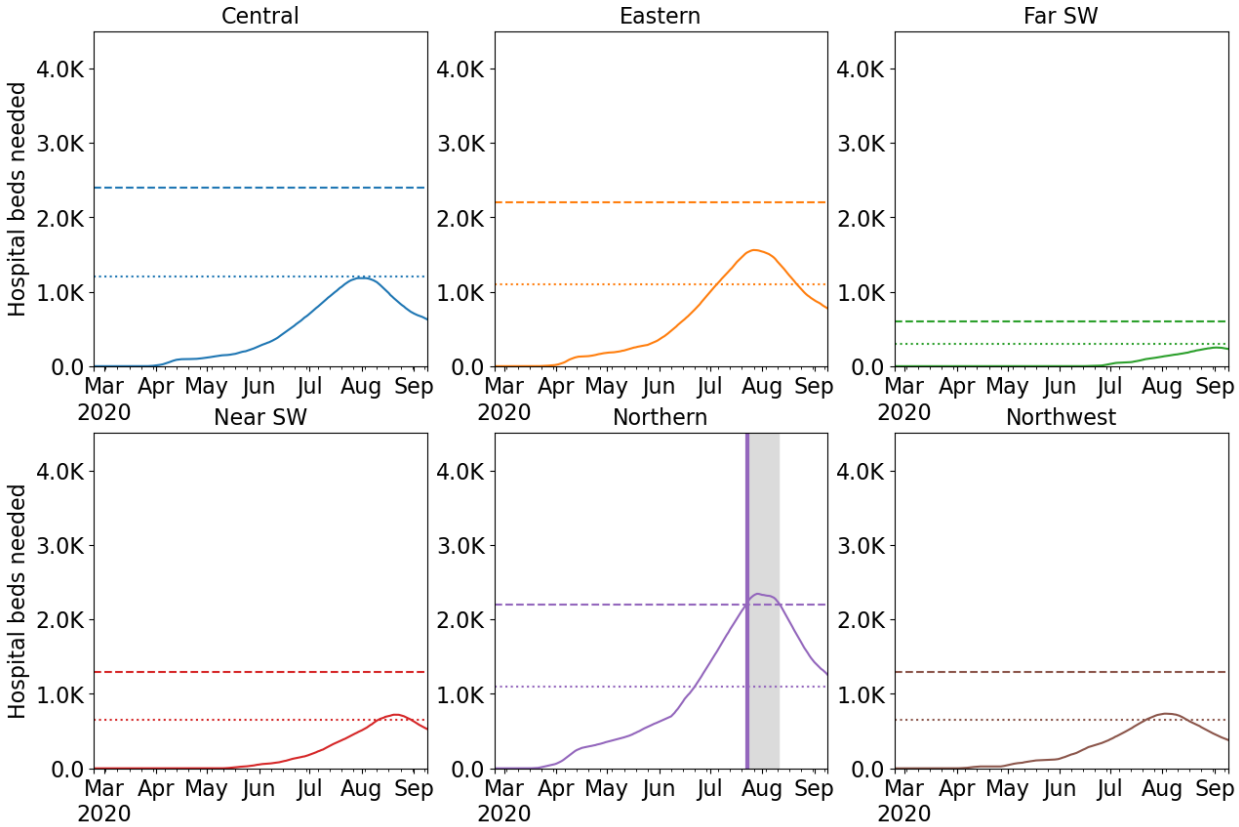
*Numbers are medians of projections

UNIVERSITY of VIRGINIA
BIOCOMPLEXITY INSTITUTE

Hospital Demand and Capacity by Region

Capacities by Region – Light Rebound

COVID-19 capacity ranges from 80% (dots) to 120% (dash) of total beds



* Assumes average length of stay of 8 days

Date ranges when regions are estimated to exceed surge capacity

	Scenario	Date Ranges
1	Strong	Early July to Late August
2	Light	Late July to Early Aug
3	Strong – Better Detection	None
4	Light – Better Detection	None
5	Full Rebound	Mid June to Early August

Social Distancing postponed the time to when capacity could be exceeded, but without other measures we may still reach it in some areas
